

Tutorial for 1D hybrid (kinetic ions/massless fluid electrons) simulation code

Kyungguk Min¹ & Kaijun Liu²

¹Korea Astronomy & Space Science Institute, Korea

²Southern University of Science and Technology, China

Materials found at:

<https://gitlab.com/kyungguk/hybrid-code-tutorial>

Hierarchy

1) Individual particles: Klimontovich equation

2) Kinetic: $f = f(\mathbf{v}, \mathbf{x}, t)$

- Eulerian: Full Vlasov solvers

$$\frac{df}{dt} = \frac{\partial f}{\partial t} + \mathbf{v} \cdot \frac{\partial f}{\partial \mathbf{x}} + \frac{q}{m} \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) \cdot \frac{\partial f}{\partial \mathbf{v}} = 0$$

- Lagrangian: Particle-in-cell codes (where PSD is represented by simulation "marker" particles)
- Darwin, gyro-kinetic, drift kinetic, etc.

3) Hybrid

- One species kinetic, the other fluid; low-frequency approx. of EM fields
- Typically kinetic ions and inertial-less, quasi-neutral fluid electrons

4) Fluid

- MHD

Hybrid Codes

- Hybrid codes arise from the need to model phenomena that do not resolve processes that occur on electron scales.
- Relevant scales: Ion gyro-radius, ion inertial spatial scales, and inverse ion gyro-frequency time scale.
- A full-dynamics PIC code must resolve electron dynamics at scales far smaller than that for ions, even though it is not relevant to the physical problems to be addressed.
- The hybrid approach differs from PIC in that
 - The displacement current is neglected in Ampère-Maxwell's law, eliminating the propagation of light waves;
 - The electrons are modeled as a massless charge-neutralizing fluid; and
 - The electric field is calculated from the generalized Ohm's law.

Governing Equations

- Ion dynamics

$$m_i \frac{d\mathbf{v}_p}{dt} = q_i \left(\mathbf{E} + \frac{\mathbf{v}_p}{c} \times \mathbf{B} \right)$$

$$\frac{d\mathbf{x}_p}{dt} = \mathbf{v}_p$$

- Electron dynamics $\rightarrow \mathbf{E}(n_e, \mathbf{V}_e, P_e, \mathbf{B})$: No explicit time dependence

$$n_e m_e \frac{d\mathbf{V}_e}{dt} = 0 = -en_e \left(\mathbf{E} + \frac{\mathbf{V}_e}{c} \times \mathbf{B} \right) - \nabla P_e$$

- Equation of state: $d(P_e/n_e^\gamma)/dt = 0$

- Quasi-neutrality: $q_e n_e = q_i n_i$

- Ampere's law

$$\nabla \times \mathbf{B} = \frac{4\pi}{c} J + \cancel{\frac{\partial \mathbf{E}}{\partial t}}$$

- Faraday's law

$$\frac{\partial \mathbf{B}}{\partial t} = -c(\nabla \times \mathbf{E})$$

Typical Update Cycle and the Challenge

- Ion acceleration: Assume at time step N , \mathbf{x}_p^N , \mathbf{E}^N , and \mathbf{B}^N are known.

$$\mathbf{v}_p^{N+1/2} = \mathbf{v}_p^{N-1/2} + \frac{q_i \Delta t}{m_i} \left(\mathbf{E}^N + \frac{\mathbf{v}_p^N}{c} \times \mathbf{B}^N \right)$$

$$\mathbf{x}_p^{N+1} = \mathbf{x}_p^N + \mathbf{v}_p^{N+1/2} \Delta t$$

- Collect current at $N + 1/2$ and density at $N + 1$.
- Update \mathbf{B} by a half-time step.

$$\mathbf{B}^{N+1/2} = \mathbf{B}^N - \frac{c \Delta t}{2} (\nabla \times \mathbf{E}^N)$$

- Calculate \mathbf{E} using the quantities at $N+1/2$.

$$\begin{aligned} \mathbf{E}^{N+1/2} &= -\frac{\mathbf{V}_i^{N+1/2}}{c} \times \mathbf{B}^{N+1/2} - \frac{\nabla P_e^{N+1/2}}{q_i n_i^{N+1/2}} - \frac{\mathbf{B}^{N+1/2} \times (\nabla \times \mathbf{B}^{N+1/2})}{4\pi q_i n_i^{N+1/2}} \\ &= \mathbf{E}(\mathbf{B}^{N+1/2}, n_i^{N+1/2}, \mathbf{V}_i^{N+1/2}) \end{aligned}$$

- Update \mathbf{B} by a half-time step.

$$\mathbf{B}^{N+1} = \mathbf{B}^{N+1/2} - \frac{c \Delta t}{2} (\nabla \times \mathbf{E}^{N+1/2})$$

- To complete the cycle, we need \mathbf{E} at $N+1$, but \mathbf{V}_i^{N+1} is not known.
- The evolution of hybrid codes has been developing a good algorithm that best calculates \mathbf{E} at the time step when the velocity is not available.

Algorithm 1: Predictor-corrector Method

- Execute one or more of provisional updates to fine-tune \mathbf{E} at the desired time step.
 - Pros: Implementation is straightforward.
 - Cons: This involves multiple provisional particle pushes which are the most time-consuming part in PIC-type code.
- Basic idea:
 1. Make a prediction of the fields at $N+1$
 2. Advance particles in the predicted field to get the ion source terms
 3. Use current and density to compute predicted fields at $N+3/2$
 4. Determine corrected field at $N+1$

Algorithm 2: Current Advanced Method

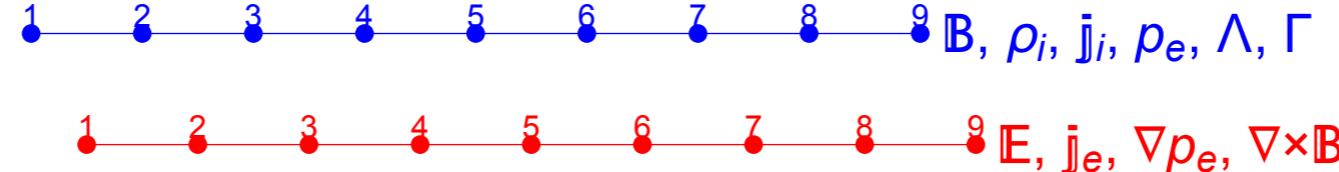

- Since the problem is not knowing \mathbf{V}_i^{N+1} , one can extrapolate \mathbf{V}_i^{N+1} using previously saved values.
- The most popular approach along that line is to calculate the current at $N+1$ by doing an extra half-time step push.

$$\mathbf{V}'_i^{N+1} = \mathbf{V}_i^{N+1/2} + \frac{\Delta t q_i}{2m_i} \left(\mathbf{E}^* + \frac{\mathbf{V}_i^{N+1/2}}{c} \times \mathbf{B}^{N+1} \right)$$
$$\mathbf{E}^* = \mathbf{E}(\mathbf{B}^{N+1}, n_i^{N+1}, \mathbf{V}_i^{N+1/2})$$

- Because the current is defined at grid points, this extra step is trivial. And yet, it results in good energy conservation.

Demo Code

- The demo code is 1.5D (one-dimensional dependence and all three components of the field vectors).
- It assumes a uniform, homogeneous, collisionless, magnetized, quasi-neutral plasma.
- Both Predictor-corrector (Kunz et al., 2014) and CAM-CL (Matthew, 1994) algorithms are implemented.
- PIC technique and implementation are based on the full-dynamics code written by Liu (2007).
- Particles are advanced using the usual leap-frog algorithm with Boris push.
- **B** and **E** are saved at staggered grid points as follows:

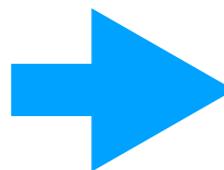

- Other quantities are defined so as to the 2nd-order centered difference makes sense as much as possible.
- All vector components are placed at the same grid point (not entirely Yee lattice).
- Three-point Hamming filter is applied to source terms to reduce grid-scale fluctuations:

$$\Phi_j^{filtered} = \frac{1}{4} \left(\Phi_{j-1}^{source} + 2\Phi_j^{source} + \Phi_{j+1}^{source} \right)$$

Change of Variables

$$\left\{ \begin{array}{l} \frac{q_0}{m_0 c} \mathbf{E} = \vec{\Xi} \\ \frac{q_0}{m_0 c} \mathbf{B} = \vec{\Omega} \\ \frac{4\pi q_0}{m_0} \rho = \Pi \\ \frac{4\pi q_0}{m_0 c} \mathbf{J} = \vec{\mathcal{J}} \\ \frac{4\pi q_0^2}{m_0^2 c^2} P_e = \mathcal{P}_e \\ \omega_s = \sqrt{\frac{4\pi q_s^2 n_s(0)}{m_s}} \\ \Omega_s = \frac{q_s B_0}{m_s c} \end{array} \right.$$

$$\left\{ \begin{array}{l} \Pi_e = -\Pi_i = -\sum_{s \neq e} \Pi_s & \text{Charge neutrality} \\ \frac{\partial \vec{\Omega}}{\partial t} = -c \nabla \times \vec{\Xi} & \text{Faraday's law} \\ \vec{\mathcal{J}} = c \nabla \times \vec{\Omega} & \text{Ampere's law} \\ \vec{\Xi} = \frac{1}{\Pi_i} \left[(\vec{\mathcal{J}} - \vec{\mathcal{J}}_i) \times \vec{\Omega} - c \nabla \mathcal{P}_e \right] & \text{Generalized Ohm's law} \\ \frac{d\mathbf{x}_p}{dt} = \mathbf{v}_p & \text{Velocity} \\ \frac{d\mathbf{v}_p}{dt} = \frac{\Omega_s}{\Omega_0} \left(c \vec{\Xi} + \mathbf{v}_p \times \vec{\Omega} \right) & \text{Lorentz force} \\ \frac{\partial \vec{\mathcal{J}}_i}{\partial t} = \sum_{s \neq e} \Pi_s \frac{\Omega_s}{\Omega_0} \left(\vec{\Xi} + \frac{\mathbf{V}_s}{c} \times \vec{\Omega} \right) \\ = \Lambda_i \vec{\Xi} + \vec{\Gamma}_i \times \vec{\Omega} & \text{Current Advance} \end{array} \right.$$

Background B

Bulk velocity

- Electron pressure:

$$\mathcal{P}_e(t) = \Omega_0^2 \frac{\beta_e}{2} \left(\frac{\Pi_e(t)}{\Pi_e(0)} \right)^\gamma = \Omega_0^2 \frac{\beta_e}{2} \left(-\frac{\Omega_e \Pi_i(t)}{\Omega_0 \omega_e^2} \right)^\gamma, \text{ where } \omega_e^2 = \frac{\Omega_e}{\Omega_0} \Pi_e(0)$$

Change of Variables

- With new variables, a population of ions is described by their cyclotron frequency (Ω_s), plasma frequency (ω_s) (and temperatures, etc. depending on velocity distribution functions), instead of mass, charge, and the number density.
- The electric field (Ξ) and the magnetic field (Ω) have units of frequency, and are understood to be a sum of the static and perturbed part (i.e., $\Omega = \Omega_0 + \delta\Omega$).
- Whereas, charge, current, and energy densities (or pressure) has units of frequency squared.
- The electric and magnetic field energy densities are $\Xi^2/2$ and $\Omega^2/2$, which then have units of frequency squared.
- Ω_0 denotes magnitude of the uniform background magnetic field. Time is in units of Ω_0^{-1} .
- The ratio Ω_s/Ω_0 describes the kind of ions. As an example, if $\Omega_p/\Omega_0 = 2\pi$, protons gyrate once per Ω_0^{-1} . For He^+ , this ratio is then $2\pi/4$; and for He^{2+} , it is $2\pi/2$.

Magnetic Field Update

x-direction
→

$$j= \begin{array}{cccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \end{array} \mathbb{B}, \rho_i, \mathbf{j}_i, p_e, \Lambda, \Gamma$$

$$j= \begin{array}{cccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \end{array} \mathbb{E}, \mathbf{j}_e, \nabla p_e, \nabla \times \mathbb{B}$$

- Magnetic field

$$\begin{cases} \Omega_{x;j}^{t+\Delta t} - \Omega_{x;j}^t = 0; \\ \Omega_{y;j}^{t+\Delta t} - \Omega_{y;j}^t = \frac{c\Delta t}{\Delta x} \left(+\Xi_{z;j-0}^{t+\Delta t/2} - \Xi_{z;j-1}^{t+\Delta t/2} \right); \\ \Omega_{z;j}^{t+\Delta t} - \Omega_{z;j}^t = \frac{c\Delta t}{\Delta x} \left(-\Xi_{y;j-0}^{t+\Delta t/2} + \Xi_{y;j-1}^{t+\Delta t/2} \right). \end{cases}$$

Or

$$\begin{cases} B_{x;j}^{t+\Delta t} - B_{x;j}^t = 0; \\ B_{y;j}^{t+\Delta t} - B_{y;j}^t = \frac{c\Delta t}{\Delta x} \left(+E_{z;j-0}^{t+\Delta t/2} - E_{z;j-1}^{t+\Delta t/2} \right); \\ B_{z;j}^{t+\Delta t} - B_{z;j}^t = \frac{c\Delta t}{\Delta x} \left(-E_{y;j-0}^{t+\Delta t/2} + E_{y;j-1}^{t+\Delta t/2} \right). \end{cases}$$

// BField.cc

```

        //
        Ei /= Real{rho[i+1] + rho[i+0]}*0.5;
    }
}
```

Velocity Moments

- Solving field equations only requires quantities weighted by a velocity distribution function and summed over velocity space.

0th: $n_s = \langle 1 \rangle_s = \int (1) f_s(t, \mathbf{x}, \mathbf{v}) d^3\mathbf{v} \longrightarrow \text{Charge density} = q_s \langle 1 \rangle_s$

1st: $n_s \mathbf{V}_s = \langle \mathbf{v} \rangle_s = \int (\mathbf{v}) f_s(t, \mathbf{x}, \mathbf{v}) d^3\mathbf{v} \longrightarrow \text{Current density} = q_s \langle \mathbf{v} \rangle_s$

2nd: $\langle \mathbf{v}\mathbf{v} \rangle_s = \int (\mathbf{v}\mathbf{v}) f_s(t, \mathbf{x}, \mathbf{v}) d^3\mathbf{v}$
→ Kinetic energy density = $m_s \sum_{j=x,y,z} \left\langle \frac{v_j^2}{2} \right\rangle_s$

→ Pressure Tensor $= m_s \left(\langle \mathbf{v}\mathbf{v} \rangle_s - n_s \mathbf{V}_s \mathbf{V}_s \right)$

- How can velocity moments be obtained? More generally, what does the operation $\langle \dots \rangle$ mean in a PIC code?

Velocity Moments (cont'd)

- Imagine equally-spaced simulation grid points.
- Initially, the number density $n_s(0)$ is spatially uniform and the particle velocity distribution is represented by $N_c = 10$ marker (simulation) particles.

t = 0

| $j - 1$ | j Cell | $j + 1$ |
|---------|----------|---------|
| 10 | 10 | 10 |

- Over time, some particles will leave the j cell; Likewise, some also enter the j cell.

t > 0

| $j - 1$ | j Cell | $j + 1$ |
|---------|----------|---------|
| 20 | 5 | 10 |

$$n_s(t) = 2 \times n_s(0)$$

$$n_s(t) = 1 \times n_s(0)$$

$$n_s(t) = 0.5 \times n_s(0)$$

- In the figure above, the number of particles in the j th cell decreased by a factor of 2; that means $n_s(t)$ there is also half of the initial value.
- Formally,

$$\frac{n_{s;j}(t)}{n_s(0)} = \sum_{p=1}^{N_{s,p}} \frac{S(x_{s,p}(t) - X_j)}{N_{c,s}}$$

Shape function

$$n_s = \langle 1 \rangle_s = \int (1) f_s d^3v$$

Velocity Moments (cont'd)

$$\frac{\int (1) f_s(t, \mathbf{x}, \mathbf{v}) d^3v}{n_s(0)} = \frac{\sum_{p=1}^{N_{s,p}} (1) S(x_{s,p}(t) - X_j)}{N_{c,s}}$$

Generalization

$$\langle \dots \rangle_s = \int (\dots) f_s(t, \mathbf{x}, \mathbf{v}) d^3v = n_s(0) \frac{\sum_{p=1}^{N_{s,p}} (\dots) S(x_{s,p}(t) - X_j)}{N_{c,s}}$$

$$\omega_s^2 = \frac{4\pi q_s^2 n_s(0)}{m_s} = \frac{\Omega_s}{\Omega_0} \Pi_s(0)$$

$$\Pi_{i;j}(t) = \sum_{s \neq e} \frac{\Omega_0}{\Omega_s} \omega_s^2 \langle 1 \rangle'_s$$

$$\vec{\mathcal{J}}_{i;j}(t) = \sum_{s \neq e} \frac{\Omega_0}{\Omega_s} \frac{\omega_s^2}{c} \langle \mathbf{v} \rangle'_s$$

$$\mathcal{E}_{i;j}(t) = \sum_{s \neq e} \frac{\Omega_0^2}{\Omega_s^2} \frac{\omega_s^2}{c^2} \langle v^2/2 \rangle'_s$$

where

$$\langle \dots \rangle'_s = \frac{\langle \dots \rangle_s}{n_s(0)} = \frac{\sum_{p=1}^{N_{s,p}} (\dots) S(x_{s,p}(t) - X_j)}{N_{c,s}}$$

Velocity Moments (cont'd)

```

/// simulation time t = dt*Nt  
///  
constexpr unsigned outer_Nt = 1000;
```

Outer loop

```
// driver.cc  
void H1D::Driver::operator()() const  
{  
    long step_count{};  
    for (long i_step = 1; i_step <= Input::outer_Nt; ++i_step) {  
        // advance simulation  
        //  
        domain->advance_by(Input::inner_Nt); Inner loop  
        // update step count  
        //  
        long const steps = step_count += Input::inner_Nt;  
        // record data  
        //  
        for (auto &pair : recorders) {  
            if (pair.second) {  
                pair.second->record(*domain, steps);  
            }  
        }  
    }  
}
```
